

FRONT END DEVELOPER SITE BUILD

INTERVIEW PART : 1

ABOUT OUR DEVELOPMENT

MPF provides creative solutions to a wide range of business problems across sectors in health, entertainment, food and alcohol, finance and apparel. Our front end developers need to be able to build beautiful, accessible, performant interfaces using a wide range of technologies. We may build a financial statistics website led by an opinionated design system, we may invent a 3D exercise player to animate motion-capture data, and everything in-between.

ABOUT THE EXERCISE

In this first exercise we will ask you to build us a website which satisfies a number of requirements, but anything not mentioned is being left purposely vague. As long as you satisfy the requirements, any other decision is up to you - but we will ask you to explain each of your decisions.

You will build a website for fans to engage with a topic. At a minimum, your site will read from an API and let the user save and group their favourites, writing their choices to storage.

How you build it, what you build, what the design is, and what features you include is up to you, however we do not expect applicants to spend more than 2 hours on this task. We will be looking to make sure that the user has proficiently met the minimum requirements, and which of the optional tasks they decided to include within the 2 hours.

You may use AI to build this, either partially or wholly.

MINIMUM REQUIREMENTS

Your site must include the following:

1 WEBSITE & FRAMEWORK

You should build a website of at least 2 pages that responsively targets a laptop up to a desktop. It should use a framework of your choice, such as React or Vue (and optionally a meta framework such as Next or Nuxt). It should implement some level of state management to manage the data and UI.

2 API USAGE

Your site must connect to an API to read data. You can use any API of your choice, as long as it provides data for multiple entities, such as:

1. Pokemon, using pokeapi.co
2. Movie and/or TV, using themoviedb.org
3. Countries, using restcountries.com

3 DATA FEATURES

Your site must enable users to search for entities in the API, mark them as their favourite, and group them. They should also be able to delete their groups and favourites.

4 STORAGE

Your site must store the user's groups and favourites, so that the user can return to the site to see and continue favouriting.

5 HOSTING AND CODE

Your site must be hosted online for us to see, and the code must be hosted in a code repository that you can provide us access to. You can of course use free hosting and a free code repository - the choice of providers will not be evaluated.

Just after starting the exercise, please commit your blank framework setup. Then please commit your final work when you have completed the exercise.

6 DOCUMENTATION

Your codebase should include a README.md that includes:

1. How to run the project locally (commands, dependencies, node versions).
2. A brief summary of your architectural decisions, choice of framework/libraries, and trade-offs made due to the 2-hour time limit.
3. Any features or refactors you would implement if given more time.

OPTIONAL

We do not expect all of these to be completed, instead these are optional items you can consider if there is available time after the minimum requirements have been met.

1 DESIGN

No designs are being provided for this exercise, however MPF is a design and UX driven company. We do not expect our front end developers to be designers, but any efforts put into the user experience and design will be noted.

2 ANIMATIONS

Animations, even micro-transitions, can improve the feel of a project. Any effort put in to include animations will be noted.

3 ERROR HANDLING

Your app could include gracefully handling API loading states, network errors, and empty search results (e.g., no blank screens or unhandled console crashes).

4 RESPONSIVENESS

Your app could be built to work on mobile and small devices, including touch instead of mouse controls.

5 ACCESSIBILITY

You could add accessibility to your site, from semantic and structural html to aria and accessible labelling.

6 TESTING

You could add unit and even E2E / UI testing, to show that your code is stable and dependable.

7 CI/CD & AUTOMATION

You could add actions / pipelines to build and deploy your solution.

EVALUATING

EVALUATION PROCESS

We will evaluate the exercise by:

1. Reviewing the site you built, how it behaves and to see what you included and what your overall approach was.
2. Reviewing the codebase for the factors listed below.
3. Reviewing your CI/CD, automation and testing (if any).

The items in #3 are optional and will not be weighted if not included.

EVALUATION FACTORS

The following is a priority list of evaluation factors. Items listed higher are considered more important and will be weighed more heavily when we evaluate your site.

1. **Architecture & Code Structure**
How well is the application structured? Despite the fact that this is likely to be a simple site, we will look for logical component separation, clean directory organization, separation of concerns (e.g., keeping data-fetching/business logic separate from presentation components), and reusability.
2. **Framework familiarity and usage**
We will evaluate the usage of your chosen framework for adherence to standards in the framework you chose.
3. **What did you build?**
We will evaluate what you built. For example, did you include a menu and routers, or did you just create a link to switch pages? Did you use icons for favouriting, or text? What fonts did you use? We will ask ourselves these questions as we look over what you built.
4. **State Management & Data Flow**
How predictable is the application state? We evaluate how data flows through the application, whether state is mutated cleanly, and if the global vs. local state boundary is well-defined.
5. **User Experience & Responsiveness**
How does the app feel to use? We evaluate layout responsiveness across mobile and desktop viewports, basic keyboard navigation/accessibility (if you've included this optional factor), and intuitive interactive feedback (button states, load indicators). This is not a design review, but rather shows that you understand the basics of making something usable.
6. **Type Safety & Code Standards**
How maintainable and readable is the code? We look for strict type safety, consistent code formatting/linting, adherence to framework idiomatic patterns, and semantic HTML structure.

7. **Communication and validation**

We will read the documentation you provide and the rationale for what you built.

8. **AI Usage**

You may use AI to produce your work - even in full - though understand that if you do we will balance the priorities slightly. MPF is an AI first company that champions the use of AI coding, and therefore we expect that developers who use generative AI to provide better solutions, thought leadership and creative thinking with their time instead.
